Introduction

- Setting:
 - off-policy \rightarrow learn about v_π while behaving according to a *behaviour policy* μ
 - linear function approximation: $v_\pi(S_t) \approx \theta_t^T \phi(S_t)$
- Goal:

Create a weighting equivalent to the **followon distribution**, which weights states according to how often they would occur prior to termination by discounting if the target policy was followed.
- Focus:

Prove stability of the resulting algorithm, the *emphatic TD*(λ): the expected update is a contraction involving a positive definite matrix

On-policy stability of TD(0) (1)

- Rewrite the TD(0) update to highlight stability issue:

$$\begin{aligned}\theta_{t+1} &= \theta_t + \alpha \left(R_{t+1} + \gamma \theta_t^T \phi(S_{t+1}) - \theta_t^T \phi(S_t) \right) \phi(S_t) \\ &= \theta_t + \alpha \left(\underbrace{R_{t+1} \phi(S_t)}_{b_t \in \mathbb{R}^n} - \underbrace{\phi(S_t)(\phi(S_t) - \gamma \phi(S_{t+1}))}_{A_t \in \mathbb{R}^{n \times n}} \right) \\ &= (I - \alpha A_t) \theta_t + \alpha b_t\end{aligned}\tag{1}$$

- Only A_t multiplies θ and is therefore critical for convergence

Idea

Suppose A_t diagonal. If A_t has some negative values, then the corresponding elements of $(I - \alpha A_t)$ will be greater than one thus increasing θ_t , leading to divergence. In general, θ_t will be reduced toward zero whenever A_t is positive definite.

On-policy stability of TD(0) (2)

Stability: Defined $A = \lim_{t \rightarrow \infty} \mathbb{E}[A_t]$ and $b = \lim_{t \rightarrow \infty} \mathbb{E}[b_t]$, a stochastic algorithm in the form of (1) is stable if the corresponding deterministic algorithm

$$\theta_{t+1} = \theta_t + \alpha(b - A\theta_t)$$

converges to unique fixed point independent form θ_0

$$\begin{aligned} A &= \lim_{t \rightarrow \infty} \mathbb{E}[A_t] \\ &= \Phi^T \underbrace{D_\pi(I - \gamma P_\pi)}_{\text{key matrix}} \Phi \end{aligned}$$

Following Sutton(1988) and Varga(1962), to assure the key matrix is positive definite we want to show that all his columns sum to a nonnegative number

On-policy stability of TD(0) (3)

To compute the columns sums:

$$\begin{aligned} \mathbf{1}^T D_\pi (I - \gamma P_\pi) &= d_\pi^T (I - \gamma P_\pi) \\ &= d_\pi^T - \gamma d_\pi^T P_\pi \\ &= d_\pi^T - \gamma d_\pi^T \\ &= (1 - \gamma) d_\pi \end{aligned}$$

all components of which are positive.

Instability of Off-policy TD(0)

- Importance sampling ratios $\rho_t = \frac{\pi(A_t|S_t)}{\mu(A_t|S_t)}$
- Off-policy TD(0) update:

$$\begin{aligned}\theta_{t+1} &= \theta_t + \alpha \rho_t \left(R_{t+1} + \gamma \theta_t^T \phi(S_{t+1}) - \theta_t^T \phi(S_t) \right) \phi(S_t) \\ &= \theta_t + \alpha \left(\underbrace{\rho_t R_{t+1} \phi_t}_{b_t} - \underbrace{\rho_t \phi_t (\phi_t - \gamma \phi_{t+1})^T}_{A_t} \theta_t \right)\end{aligned}$$

- And thus the matrix A becomes

$$A = \lim_{t \rightarrow \infty} \mathbb{E}[A_t] = \Phi^T D_\mu (I - \gamma P_\pi) \Phi$$

Instability of Off-policy TD(0): Example

- $r = 0$ for every transition

$$\lambda = 0$$
$$\gamma = 0.9$$

$$\mu(\text{right}|\cdot) = 0.5$$
$$\pi(\text{right}|\cdot) = 1$$

- Columns of the key matrix may sum to negative number

$$\mathbf{D}_\mu(\mathbf{I} - \gamma \mathbf{P}_\pi) = \begin{bmatrix} 0.5 & 0 \\ 0 & 0.5 \end{bmatrix} \times \begin{bmatrix} 1 & -0.9 \\ 0 & 0.1 \end{bmatrix} = \begin{bmatrix} 0.5 & -0.45 \\ 0 & 0.05 \end{bmatrix}.$$

- Effect on updates ($\theta_0 = 10$):

$$\begin{aligned}\theta_{t+1} &= \theta_t + \rho_t \alpha \left(R_{t+1} + \gamma \theta_t^\top \phi_{t+1} - \theta_t^\top \phi_t \right) \phi_t \\ &= 10 + 2 \cdot 0.1 (0 + 0.9 \cdot 10 \cdot 2 - 10 \cdot 1) 1 \\ &= 10 + 1.6,\end{aligned}$$

$$\begin{aligned}\theta_{t+1} &= \theta_t + \rho_t \alpha \left(R_{t+1} + \gamma \theta_t^\top \phi_{t+1} - \theta_t^\top \phi_t \right) \phi_t \\ &= 10 + 2 \cdot 0.1 (0 + 0.9 \cdot 10 \cdot 2 - 10 \cdot 2) 2 \\ &= 10 - 0.8.\end{aligned}$$

Since these updates happen with same frequency ($d_\mu = [0.5, 0.5]$) a divergence occurs.

Off-policy stability of emphatic TD(0) (1)

- Followon trace:

$$F_t = \gamma \rho_{t-1} F_{t-1} + 1 \quad \forall t > 0, F_0 = 1$$

- So the TD(0) update becomes:

$$\begin{aligned}\theta_{t+1} &= \theta_t + \alpha F_t \rho_t (R_{t+1} \phi_t + \gamma \theta_t^T \phi_{t+1} - \theta_t^T \phi_t) \phi_t \\ &= \theta_t + \alpha \left(\underbrace{F_t \rho_t R_{t+1} \phi_t}_{b_t} - \underbrace{F_t \rho_t \phi_t (\phi_t - \gamma \phi_{t+1})^T \theta_t}_{A_t} \right)\end{aligned}$$

- The expected A matrix thus becomes:

$$A = \lim_{t \rightarrow \infty} \mathbb{E}[A_t] = \Phi^T F (I - \gamma P_\pi) \Phi$$

where F is the diagonal matrix with diagonal elements $f(s) = d_\mu \lim_{t \rightarrow \infty} \mathbb{E}_\mu[F_t | S_t = s]$ components of the vector f given by

$$f = (I - \gamma P_\pi^T)^{-1} d_\mu$$

Off-policy stability of emphatic TD(0) (2)

- f is the expected number of steps that would be spent in each state during an excursion starting from the behaviour distribution d_μ and following π
- in the $\theta \rightarrow 2\theta$ example, the F matrix is

$$F = \begin{bmatrix} 0.5 & 0 \\ 0 & 0.95 \end{bmatrix}$$

$$f(1) = d_\mu(1) = 0.5$$

$$f(2) = d_\mu(2) = 0.5 + 0.9 + 0.9^2 + \dots = 9.5$$

thus giving much more importance to the lower row

- what's the effect of F in the key matrix?

off-policy TD(0)

$$D_\mu(I - \gamma P_\pi) = \begin{bmatrix} 0.5 & -0.45 \\ 0 & 0.5 \end{bmatrix}$$

off-policy emphatic TD(0)

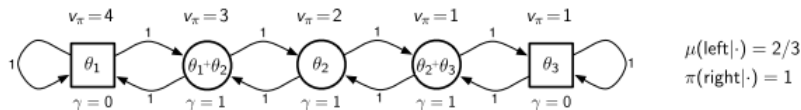

$$F(I - \gamma P_\pi) = \begin{bmatrix} 0.5 & -0.45 \\ 0 & 0.95 \end{bmatrix}$$

Generalizations I

- **discount function** $\gamma : S \rightarrow [0, 1]$ such that $\prod_{k=1}^{\infty} \gamma(S_t + k) = 0$ w.p. 1 $\forall t$. Allows soft termination:

$$G_t = R_{t+1} + \gamma(S_{t+1})T_{t+2} + \gamma(S_{t+1})\gamma(S_{t+2})R_{t+3} + \dots$$

thus, if $\gamma(S_k) = 0$, the rewards accumulation is fully terminated at step $k > t$

- **interest function** $i : S \rightarrow [0, \infty)$: explicitly specify states for which we want accurate estimates of value. The MSVE objective function thus becomes

$$MSVE(\theta) = \sum_{s \in S} d_{\mu}(s) i(s) \left(v_{\pi}(s) - \theta^T \phi(s) \right)^2$$

- **Bootstrapping function** $\lambda : S \rightarrow [0, 1]$
